

### <u>HFlush</u>

### **Realtime Flushing for Modern Storage Environments**

Jaime Cernuda, Hugo Trivino, Hariharan Devarajan, Anthony Kougkas, Xian-He Sun

#### **OVERVIEW**

#### History

- →A disparity in speedup between CPU and Storage access time has created what is known as the I/O bottleneck.
- →To solve this issue, traditional solutions have involved data buffering and aggregations on fast storage mediums.
- →However, faster tiers of data storage, such as RAM, have lower storage capacity which eventually require eviction of data to a lower tier, traditionally a Parallel File System (PFS).

#### Observations

- →Current eviction solutions are event-based and stall I/O when performing evictions.
   →Evictions are initiated by individual nodes, without scalability, and provide writing patterns not favorable to the PFS.
- →Enhanced capabilities of the new storage devices (e.g., NVMe SSDs) such as increased hardware concurrency are not taken into account by existing system software.

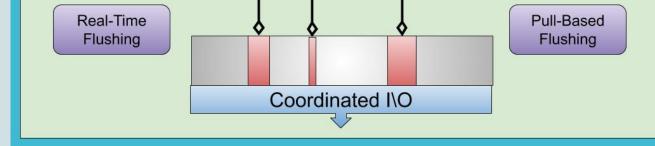

#### Approach

- →Amortize the cost of evictions into small continuous flushing operations instead of irregularly stalling I/O operations.
- →Globally coordinate all evictions to provide better writing patterns to the PFS and match the

Data-intensive						Compute-intensive				
Event-based flushing		Tim	eline	Real-time flushing		Event-based flushing		Tim	eline	Real-time flushing
Eviction Policy Write To disk	I/O I/O Comp. WORKLOADS

**INITIAL EVALUATIONS** 

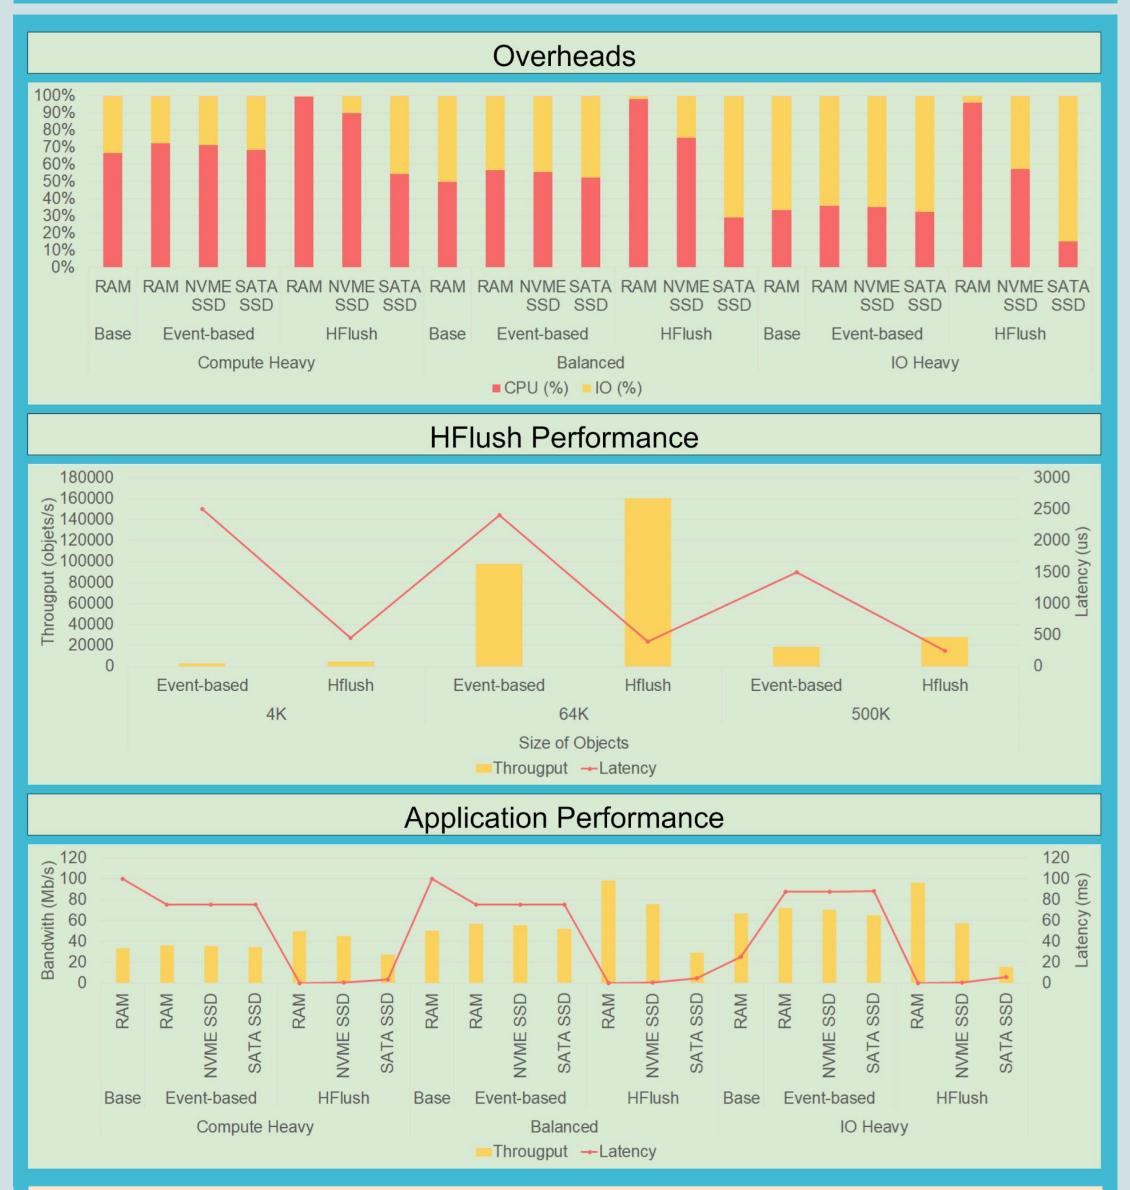

demand by offering elastic resources.

 →Leverage the hardware concurrency to perform device-specific eviction optimizations.
 →Move to a server-pull eviction model to provide a continuous stream of evictions.

#### HFLUSH DESIGN

Testbed: Ares supercomputer at the Illinois Institute of Technology

### **DESIGN IMPLICATIONS**

Leveraging a data streaming paradigm enables:

- Autoscaling
- Data durability
- Pipelined flushing in multi-tiered environments
- Matching hardware properties from source and destination

### **RELATED WORK**

- Anthony Kougkas, Hariharan Devarajan, and Xian-He Sun. 2018. Hermes: A Heterogeneous-Aware Multi-Tiered Distributed I/O Buffering System. In Proceedings of the 27th International Symposium on High-Performance Parallel and Distributed Computing (HPDC '18). ACM, New York, NY, USA.

#### **Compute Nodes:**

- CPU: Dual Intel(R) Xeon Scalable Silver 4114 @ 2.20GHz (40 nodes)
- RAM: 96 GB RAM
- Network: 10Gbit Ethernet with RoCE
- Storage: local 512GB NVMe SSD.

#### Storage Nodes:

- CPU: Two quad-core Opteron 2376 @ 2.3GHz (40 nodes)
- RAM: 32GB DDR2-667
- Storage: 1 250GB Samsung 860 Evo SATA SSD, 1TB Seagate 7200K SATA hard drive

### CONCLUSIONS

- HFlush is a pull-based data flusher that implements a continuous data eviction mechanism.
- Initial results have shown HFlush to be a promising solution to the growing challenge of extreme scale data generation, especially in case of workloads with periodic I/O or in systems that make use of modern hardware with high concurrency.
- The ability of HFlush to amortize the I/O stall time allows applications using it to significantly increase the CPU usage by over **50%**.
- The near real-time nature of the eviction provides an improved overall latency on the data flushing with 7x latency reduction and a 2X bandwidth increase over batch-based flushing solutions, which reflects in a lower I/O stall time for the application.
