This is an open book exam. You are permitted to use the textbook (hardcopy only), any class handouts, anything posted on the web page, any of your own assignments, and anything in your own handwriting. Foreign students may use a dictionary. Nothing else is permitted: No calculators, laptops, cell phones, Ipads, Ipods, communicators, GPSes, etc.!

Do all five problems in this booklet. All problems are equally weighted, so do not spend too much time on any one question.

Show your work! You will not get partial credit if the grader cannot figure out how you arrived at your answer.

1. **Probability.**

A parking lot has a row of $n$ parking spaces; $k$ cars arrive and park in random spaces. An SUV, which needs two adjacent empty parking spaces, arrives. What is the probability that the SUV can park? (*Hint:* The hardest element of this problem was problem 3 of the first exam.)
2. **Probabilistic Analysis of Duels**

Two people, $P$ and $Q$, stand opposite each other, each with a loaded pistol. Their duel proceeds in rounds: at each round $P$ fires a single shot at $Q$, whereupon $Q$ dies if hit. If $P$ misses, $Q$ fires a single shot at $P$, whereupon $P$ dies if hit. Suppose they have, respectively, probabilities $p$ and $q$ of hitting (and thus killing) their opponent and these probabilities remain constant as the duel progresses. Assume that $P$ fires first and that they never run out of bullets.

(a) Prove that the probability that $P$ kills $Q$ at the $k$th shot is $p[(1 - p)(1 - q)]^{k-1}$.

(b) Compute the probability that $P$ survives, killing $Q$.

(c) Compute the expected number of shots that $P$ fires.
3. **Conditional Probability.**

From the discussion in the lecture on February 23 we have:

\[
\Pr\{\text{breast cancer in one's forties}\} = \frac{40}{10000}
\]

\[
\Pr\{\text{positive mammogram among breast cancer patients}\} = \frac{32}{40}
\]

\[
\Pr\{\text{positive mammogram among all women}\} = \frac{1028}{10000}.
\]

Use Bayes' theorem to find the conditional probability that a woman in her forties *does* have breast cancer, given that she had a *negative* mammogram.
## 4. Linear Recurrences

Fill in the ten missing entries in the following table:

<table>
<thead>
<tr>
<th>Annihilator</th>
<th>Growth Rate</th>
<th>Sample Recurrence</th>
</tr>
</thead>
<tbody>
<tr>
<td>$(E + 2)(E - 4)$</td>
<td></td>
<td>$S_n = 2S_{n-1} + 8S_{n-2}$</td>
</tr>
<tr>
<td>$(E - 2)^2$</td>
<td>$\Theta(5^n)$</td>
<td></td>
</tr>
<tr>
<td>$(E - \phi)(E - \hat{\phi})(E - 1)^2$</td>
<td>$\Theta(3^{-n})$</td>
<td>$S_n = S_{n-1} + S_{n-2} + n$</td>
</tr>
</tbody>
</table>
5. Divide-and-Conquer Multiplication of Integers

(a) On March 23 Professor Reingold presented an algorithm to multiply two \( n \)-digit numbers in time \( T(n) \) defined by

\[
T(1) = 1 \\
T(n) = 3T(n/2) + Kn
\]

for some value of \( K \) and he showed that \( T(n) = cn + \hat{c}n^{\lg 3} = \Theta(n^{\lg 3}) \approx \Theta(n^{1.57}) \). The TA saw a way to modify the algorithm so that the time required would be described by

\[
T(1) = 1 \\
T(n) = 10T(n/4) + kn
\]

where \( k \) is much, much smaller than \( K \). Reingold said that the TA’s algorithm is inferior. Explain why.

(b) The TA then improved his algorithm so that it would only take time

\[
T(1) = 1 \\
T(n) = 25T(n/8) + 2^K n
\]

What was Reingold’s reaction (and why)?
