

Storage Allocation: Advanced

CS351: Systems Programming Day 22: Nov. 08, 2022

Instructor:

Nik Sultana

Slides adapted from Bryant and O'Hallaron

Today

Explicit free lists

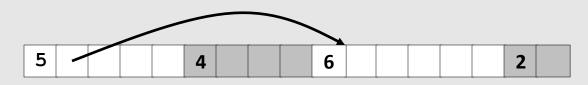

- Segregated free lists
- Garbage collection
- Memory-related perils and pitfalls

Keeping Track of Free Blocks

Method 1: Implicit free list using length—links all blocks

Method 2: Explicit free list among the free blocks using pointers

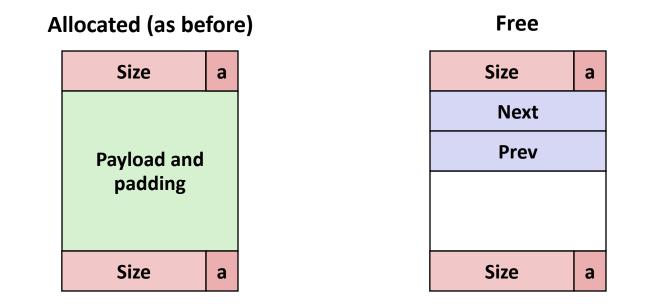

- Method 3: Segregated free list
 - Different free lists for different size classes

Method 4: Blocks sorted by size

 Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Explicit Free Lists

Maintain list(s) of *free* blocks, not *all* blocks

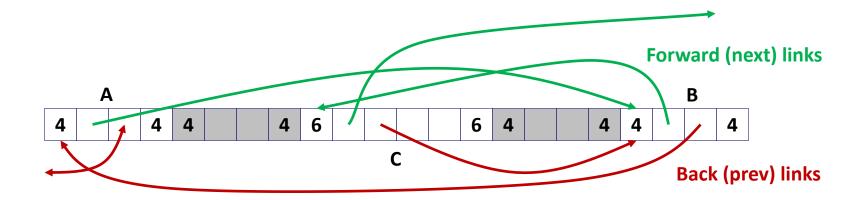

- The "next" free block could be anywhere
 - So we need to store forward/back pointers, not just sizes
- Still need boundary tags for coalescing
- Luckily we track only free blocks, so we can use payload area

Explicit Free Lists

Logically:

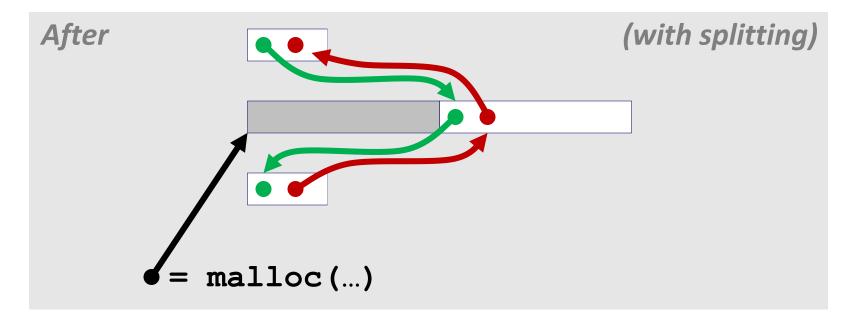

Physically: blocks can be in any order

Allocating From Explicit Free Lists

conceptual graphic

Freeing With Explicit Free Lists

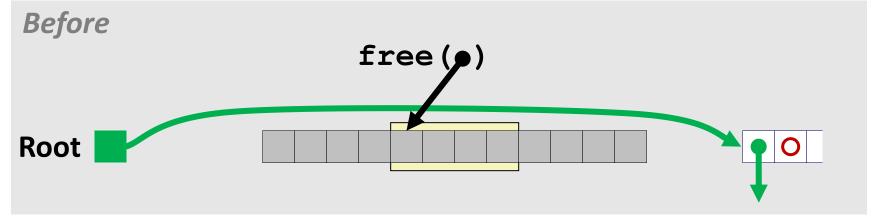

- Insertion policy: Where in the free list do you put a newly freed block?
- LIFO (last-in-first-out) policy
 - Insert freed block at the beginning of the free list
 - **Pro:** simple and constant time
 - Con: studies suggest fragmentation is worse than address ordered

Address-ordered policy

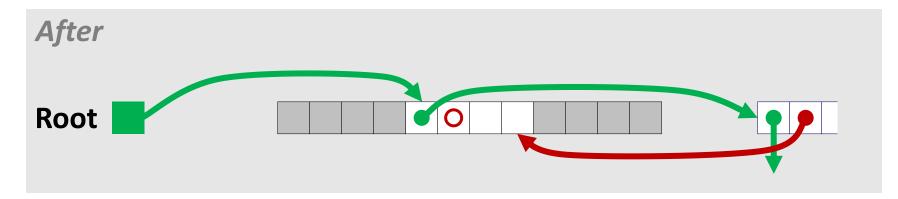

- Insert freed blocks so that free list blocks are always in address order: *addr(prev) < addr(curr) < addr(next)*
- Con: requires search
- Pro: studies suggest fragmentation is lower than LIFO

Freeing With a LIFO Policy (Case 1)

conceptual graphic

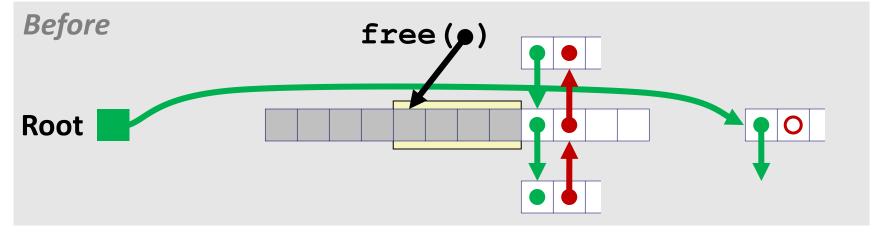

Insert the freed block at the root of the list

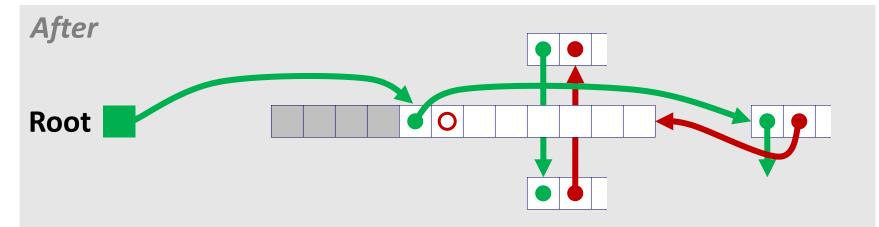

Illinois Tech CS351 Fall 2022

Freeing With a LIFO Policy (Case 2)

conceptual graphic

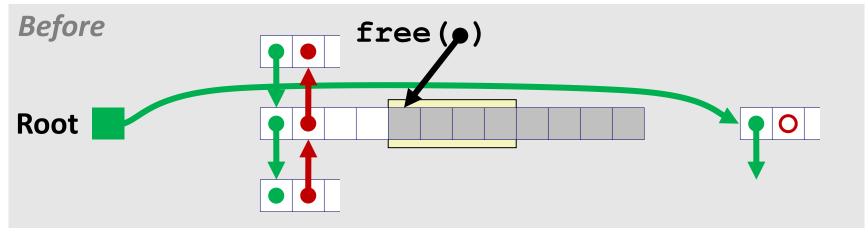

Splice out successor block, coalesce both memory blocks and insert the new block at the root of the list

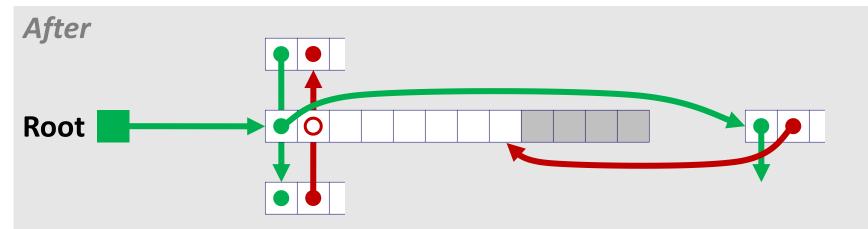

Freeing With a LIFO Policy (Case 3)

conceptual graphic

 Splice out predecessor block, coalesce both memory blocks, and insert the new block at the root of the list

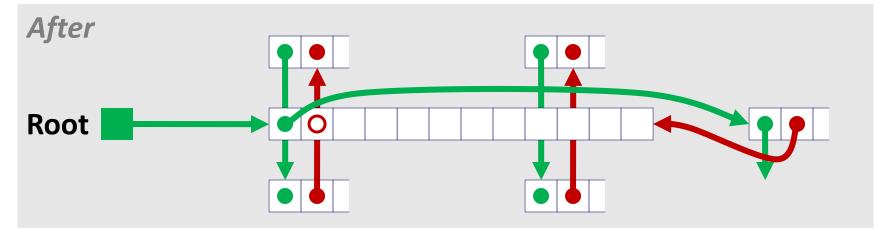

Freeing With a LIFO Policy (Case 4)

conceptual graphic

Splice out predecessor and successor blocks, coalesce all 3 memory blocks and insert the new block at the root of the list

Explicit List Summary

- Comparison to implicit list:
 - Allocate is linear time in number of *free* blocks instead of *all* blocks
 - *Much faster* when most of the memory is full
 - Slightly more complicated allocate and free since needs to splice blocks in and out of the list
 - Some extra space for the links (2 extra words needed for each block)
 - Does this increase internal fragmentation?
- Most common use of linked lists is in conjunction with segregated free lists
 - Keep multiple linked lists of different size classes, or possibly for different types of objects

Keeping Track of Free Blocks

Method 1: Implicit list using length—links all blocks

Method 2: Explicit list among the free blocks using pointers

- Method 3: Segregated free list
 - Different free lists for different size classes

Method 4: Blocks sorted by size

 Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

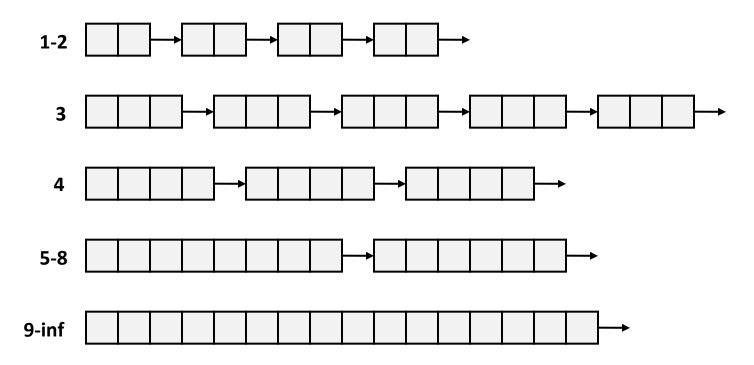

Today

Explicit free lists

- Segregated free lists
- Garbage collection
- Memory-related perils and pitfalls

Segregated List (Seglist) Allocators

Each *size class* of blocks has its own free list

- Often have separate classes for each small size
- For larger sizes: One class for each two-power size

Seglist Allocator

Given an array of free lists, each one for some size class

To allocate a block of size n:

- Search appropriate free list for block of size m > n
- If an appropriate block is found:
 - Split block and place fragment on appropriate list (optional)
- If no block is found, try next larger class
- Repeat until block is found

If no block is found:

- Request additional heap memory from OS (using sbrk())
- Allocate block of n bytes from this new memory
- Place remainder as a single free block in largest size class.

Seglist Allocator (cont.)

To free a block:

Coalesce and place on appropriate list

Advantages of seglist allocators

- Higher throughput
 - log time for power-of-two size classes
- Better memory utilization
 - First-fit search of segregated free list approximates a best-fit search of entire heap.
 - Extreme case: Giving each block its own size class is equivalent to best-fit.

More Info on Allocators

 D. Knuth, "The Art of Computer Programming", 2nd edition, Addison Wesley, 1973

The classic reference on dynamic storage allocation

Wilson et al, "Dynamic Storage Allocation: A Survey and Critical Review", Proc. 1995 Int'l Workshop on Memory Management, Kinross, Scotland, Sept, 1995.

- Comprehensive survey
- Available from CS:APP student site (csapp.cs.cmu.edu)

Today

- Explicit free lists
- Segregated free lists
- Garbage collection
- Memory-related perils and pitfalls

Implicit Memory Management: Garbage Collection

 Garbage collection: automatic reclamation of heap-allocated storage—application never has to free

```
void foo() {
    int *p = malloc(128);
    return; /* p block is now garbage */
}
```

Common in many dynamic languages:

Python, Ruby, Java, Perl, ML, Lisp, Mathematica

Variants ("conservative" garbage collectors) exist for C and C++

However, cannot necessarily collect all garbage

Garbage Collection

- How does the memory manager know when memory can be freed?
 - In general we cannot know what is going to be used in the future since it depends on conditionals
 - But we can tell that certain blocks cannot be used if there are no pointers to them

Must make certain assumptions about pointers

- Memory manager can distinguish pointers from non-pointers
- All pointers point to the start of a block
- Cannot hide pointers
 (e.g., by coercing them to an int, and then back again)

Classical GC Algorithms

Mark-and-sweep collection (McCarthy, 1960)

Does not move blocks (unless you also "compact")

Reference counting (Collins, 1960)

Does not move blocks (not discussed)

Copying collection (Minsky, 1963)

Moves blocks (not discussed)

Generational Collectors (Lieberman and Hewitt, 1983)

- Collection based on lifetimes
 - Most allocations become garbage very soon
 - So focus reclamation work on zones of memory recently allocated

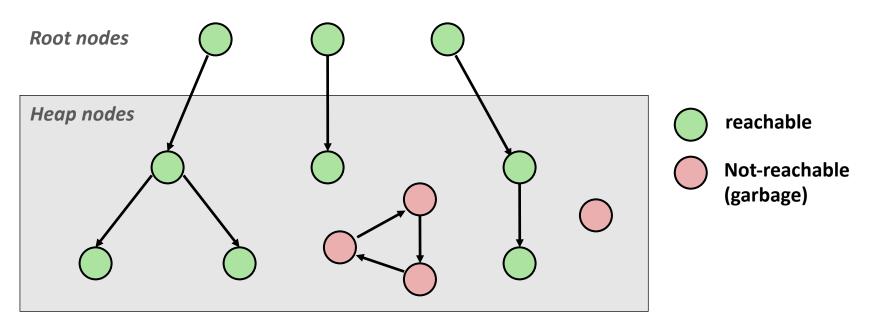

For more information:

Jones and Lin, "Garbage Collection: Algorithms for Automatic Dynamic Memory", John Wiley & Sons, 1996.

Memory as a Graph

We view memory as a directed graph

- Each block is a node in the graph
- Each pointer is an edge in the graph
- Locations not in the heap that contain pointers into the heap are called root nodes (e.g. registers, locations on the stack, global variables)

A node (block) is *reachable* if there is a path from any root to that node.

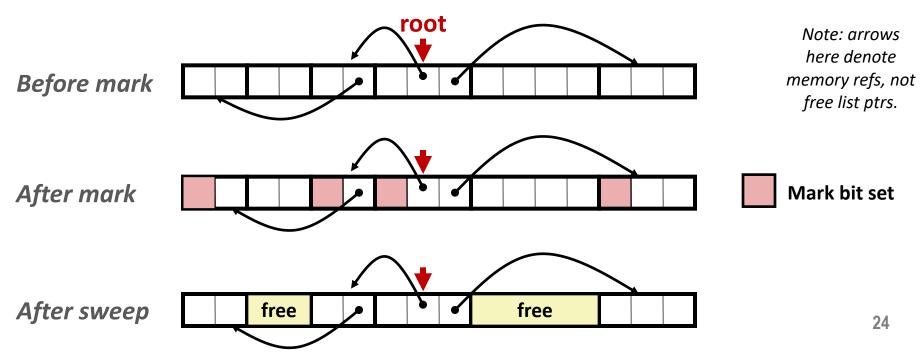

Non-reachable nodes are *garbage* (cannot be needed by the application)

Mark and Sweep Collecting

- Can build on top of malloc/free package
 - Allocate using malloc until you "run out of space"

When out of space:

- Use extra mark bit in the head of each block
- Mark: Start at roots and set mark bit on each reachable block
- Sweep: Scan all blocks and free blocks that are not marked

Assumptions For a Simple Implementation

Application

- **new(n):** returns pointer to new block with all locations cleared
- read(b,i): read location i of block b into register
- write(b,i,v): write v into location i of block b

Each block will have a header word

- addressed as b[-1], for a block b
- Used for different purposes in different collectors
- Instructions used by the Garbage Collector
 - is_ptr(p): determines whether p is a pointer
 - length (b): returns the length of block b, not including the header
 - get_roots(): returns all the roots

Mark and Sweep (cont.)

Mark using depth-first traversal of the memory graph

```
void mark(ptr p) {
   if (!is ptr(p)) return; // do nothing if not pointer
   if (markBitSet(p)) return; // check if already marked
  setMarkBit(p);
   for (i=0; i < length(p); i++) // call mark on all words</pre>
    mark(p[i]);
  return;
}
```

```
// set the mark bit
    // in the block
```

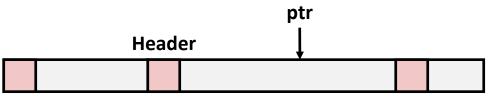

Sweep using lengths to find next block

```
void sweep(ptr p, ptr end) {
   while (p < end) {
      if markBitSet(p)
         clearMarkBit();
      else if (allocateBitSet(p))
         free(p);
      p += length(p);
}
```

Conservative Mark & Sweep in C

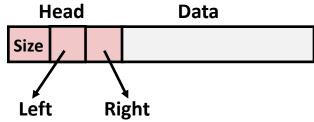

A "conservative garbage collector" for C programs

- is_ptr() determines if a word is a pointer by checking if it points to an allocated block of memory
- But, in C pointers can point to the middle of a block

So how to find the beginning of the block?

- Can use a balanced binary tree to keep track of all allocated blocks (key is start-of-block)
- Balanced-tree pointers can be stored in header (use two additional words)

Left: smaller addresses Right: larger addresses

Today

- Explicit free lists
- Segregated free lists
- Garbage collection
- Memory-related perils and pitfalls

Memory-Related Perils and Pitfalls

- Dereferencing bad pointers
- Reading uninitialized memory
- Overwriting memory
- Referencing nonexistent variables
- Freeing blocks multiple times
- Referencing freed blocks
- Failing to free blocks

C operators

Operators	Associativity
() [] -> .	left to right
! ~ ++ + - * & (type) sizeof	right to left
* / %	left to right
+ -	left to right
<< >>	left to right
< <= > >=	left to right
== !=	left to right
&	left to right
^	left to right
	left to right
& &	left to right
	left to right
?:	right to left
= += -= *= /= %= &= ^= != <<= >>=	right to left
/	left to right

->, (), and [] have high precedence, with * and & just below
 Unary +, -, and * have higher precedence than binary forms

C Pointer Declarations: Test Yourself!

int	*p	p is a pointer to int
int	*p[13]	p is an array[13] of pointer to int
int	*(p[13])	p is an array[13] of pointer to int
int	**p	p is a pointer to a pointer to an int
int	(*p) [13]	p is a pointer to an array[13] of int
int	*f()	f is a function returning a pointer to int
int	(*f)()	f is a pointer to a function returning int
int	(*(*f())[13])()	f is a function returning ptr to an array[13] of pointers to functions returning int
int	(*(*x[3])())[5]	x is an array[3] of pointers to functions returning pointers to array[5] of ints

Source: K&R Sec 5.12

Dereferencing Bad Pointers

The classic scanf bug

int val; ... scanf(``%d", val);

Reading Uninitialized Memory

Assuming that heap data is initialized to zero

```
/* return y = Ax */
int *matvec(int **A, int *x) {
    int *y = malloc(N*sizeof(int));
    int i, j;
    for (i=0; i<N; i++)
        for (j=0; j<N; j++)
            y[i] += A[i][j]*x[j];
    return y;
}</pre>
```

Allocating the (possibly) wrong sized object

```
int **p;
p = malloc(N*sizeof(int));
for (i=0; i<N; i++) {
    p[i] = malloc(M*sizeof(int));
}
```

Off-by-one error

```
int **p;
p = malloc(N*sizeof(int *));
for (i=0; i<=N; i++) {
    p[i] = malloc(M*sizeof(int));
}
```

Not checking the max string size

```
char s[8];
int i;
gets(s); /* reads "123456789" from stdin */
```

Basis for classic buffer overflow attacks

Misunderstanding pointer arithmetic

```
int *search(int *p, int val) {
  while (*p && *p != val)
     p += sizeof(int);
  return p;
}
```

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
    int *packet;
    packet = binheap[0];
    binheap[0] = binheap[*size - 1];
    *size--;
    Heapify(binheap, *size, 0);
    return(packet);
}
```

Referencing Nonexistent Variables

Forgetting that local variables disappear when a function returns

```
int *foo () {
    int val;
    return &val;
}
```

Freeing Blocks Multiple Times

Nasty!

Referencing Freed Blocks

Evil!

```
x = malloc(N*sizeof(int));
        <manipulate x>
        free(x);
            ...
y = malloc(M*sizeof(int));
        for (i=0; i<M; i++)
            y[i] = x[i]++;</pre>
```

Failing to Free Blocks (Memory Leaks)

Slow, long-term killer!

```
foo() {
    int *x = malloc(N*sizeof(int));
    ...
    return;
}
```

Failing to Free Blocks (Memory Leaks)

Freeing only part of a data structure

```
struct list {
   int val;
   struct list *next;
};
foo() {
   struct list *head = malloc(sizeof(struct list));
   head \rightarrow val = 0;
   head->next = NULL;
   <create and manipulate the rest of the list>
    . . .
   free(head);
   return;
}
```

Dealing With Memory Bugs

Debugger: gdb

- Good for finding bad pointer dereferences
- Hard to detect the other memory bugs

Data structure consistency checker

- Runs silently, prints message only on error
- Use as a probe to zero in on error

Binary translator: valgrind

- Powerful debugging and analysis technique
- Rewrites text section of executable object file
- Checks each individual reference at runtime
 - Bad pointers, overwrites, refs outside of allocated block

glibc malloc contains checking code

setenv MALLOC_CHECK_ 3

Hot off the press! <u>http://pitchfork.cs.iit.edu</u>

🛱 Pitchfork Project

The Pitchfork project developed a toolchain to implement the *privilege separation* ("privsep") technique for software security, and applied that toolchain to several examples of third-party software. Privsep involves organizing software into mutually-dependent but differently-trusted *compartments*. Compartments can be secured separately and even executed in different containers/VMs/machines.

Pitchfork and libcompart

Privilege separation (privsep) is an effective technique for improving software's security, but privsep involves decomposing software into components and assigning them different privileges. This is often laborious and errorprone. This paper contributes the following for applying privsep to C software: (1) **libcompart**: a portable, lightweight, and distributed runtime library that abstracts externally-enforced compartment isolation; (2) an abstract compartmentalization model of software for reasoning about privsep; and (3) **Pitchfork**: a privsep-aware Clang-based tool for code analysis and semi-automatic software transformation to use the runtime library.

To be presented at ACSAC 2022:

Compartment-aware Debugging

Compartmentalized software presents unique challenges to debugging because of the tension between usability, debuggability, security, and distributed systems. Compartment-Aware Debugging has been explored in 2 projects: a paper by **Henry Zhu** at APDCM and a poster by **Junyong Zhao**, and to which **Henry Zhu** contributed, at ACSAC.

Presented at APDCM 2020:

Follow-up work presented at ACSAC 2020:

Compartmentalized cURL

Systems we use daily make limited use of compartmentalization because of the engineering difficulty imposed by the compartmentalization process. We wanted to create a state-of-the-art example of a finegrained compartmentalization of cURL, a thirdparty, long-standing and very widely-used system, without compromising its performance, usability and security. This was explored in **Stephen Carrasquillo's** project, assisted in part by **Junyong Zhao** and **Henry Zhu**.

Presented at ACSAC 2020:

GAPS CLOSURE

Our project also contributed to the CLOSURE system for developing and running more secure

GAPS CLOSURE

Our project also contributed to the CLOSURE system for developing and running more secure This system release accompanies the paper "Towards Practical Application-level Support for Privilege Separation".

October 2022

Contents

Six classes of artifacts are included in this release:

1. Data and graphs from our survey of FreeBSD ports -- described in section 2.3 of the paper and in the Appendix. The data consists of text files containing columnar data. Directory: freebsd_ports_survey/data

Graphs derived from this data, shown in the paper: freebsd_ports_survey/graphs

- 2. Full scripts that were used to generate the data in (1). These were run on FreeBSD 12.2 and do not rely on special dependencies. Directory: freebsd_ports_survey/scripts
- 3. libcompart -- the library described in section 6 of the paper. This consists of portable C code, and includes build automation scripts. It was compiled and run on Linux, FreeBSD, and macOS. Directory: libcompart/compartmenting/libcompart The libcompart serializer is described in section 7.4 of the paper.

Directory: libcompart/compartmenting/libcompart_serializer

4. Examples of applying libcompart to third-party software (e.g., Evince) -- described in section 9 of the paper. Instructions are provided on which specific versions of the software were used, how to link them with libcompart, and what example output looks like. The third-party software is widely-used and well-documented. Directory: libcompart/compartmenting/. Each example has a separate README.

Per-lecture feedback

- Better sooner rather than later!
- I can help with issues sooner.
- There is a per-lecture feedback form.
- The form is anonymous. (It checks that you're at Illinois Tech to filter abuse, but I don't see who submitted any of the forms.)
- https://forms.gle/qoeEbBuTYXo5FiU1A
- I'll remind about this at each lecture.
